Growing Corn in a Computer

The Hybrid-Maize Simulation Model and its Application to Production Agriculture

Achim Dobermann
Haishun Yang

Outline

1. Definition of yield potential and yield gaps
2. Hybrid-Maize – model description and validation
3. Potential applications of Hybrid-Maize in corn management

Yield potential and yield gaps

To achieve yield potential of an environment:

- **Utilize the entire growing season (= optimal planting date and variety choice)**
- **Optimize plant population**
- **Grow the crop with minimal possible abiotic and biotic stresses (nutrients, water, pests)**

Hybrid-Maize model

- Corn specific. Simulates growth and development of corn driven by light interception and temperature.
- Simulates corn yield potential and water-limited attainable yield. Nitrogen component is in work.
- Sources: Ceres-Maize, INTERCOM, own components & modifications.
- Predicts date of silking based on GDD for a corn hybrid.
- Allows simulating single growing seasons or long-term climate data.
- Easy import of online weather data.

Authors: H. Yang, A. Dobermann, K. Cassman, J. Lindquist, T. Arkebauer, D. Walters (UNL).

Hybrid-Maize model

Input data

- Daily weather (solar radiation, max. and min. T, rainfall)
- Crop management (date of planting, GDD for hybrid, plant density, sowing depth)
- For simulating water-limited yield: max. rooting depth, texture class and bulk density in topsoil and subsoil)
- Optional: change model parameters (model uses default values, but those can be changed)
 - Hybrid-specific crop coefficients
 - Soil physical properties for different soil texture classes
 - General model coefficients describing crop growth and development

Clay Center: NSFP trial, 2002, Pioneer 33P67, furrow-irrigated

Potential applications

Using historical, long-term climate data for a site:

- Assess long-term yield potential and its variation among years (irrigated and non-irrigated).
- Assess change in yield potential due to varying planting date, hybrid choice, or plant density.
- Post-harvest analysis: what happened?

- Management decisions:
 - set adequate yield goals
 - determine optimal planting date (window)
 - identify most suitable varieties/hybrids
 - determine optimal plant density
 - evaluate economics and risks of various scenarios.

Irrigated corn at Lincoln, 114 d hybrid, Planted April 25

Lincoln, NE, based on long-term climate. At this site, high night temperatures during grain filling may cause early maturity of corn. Delaying planting or choosing a longer season hybrid could move grain filling into a period with lower night temperatures.

Can we exploit more yield potential at this site by shifting the grain filling to a cooler period?

→ plant a full-season hybrid 2-3 weeks later than normal

Northwest	7-May	2250	205	195-225	85	65-105

Simulations based on weather data collected during the past 20 years at multiple locations in each district (High Plains Regional Climate Center online database). Assumes currently widespread cropping practices (planting date, hybrid maturity, plant density) as reported by NASS.

To achieve full climatic site yield potential, management requires:

- Identify optimal growing season duration: Hybrid-Maize model searches for optimal planting data and the date when grain filling stops.
- Select a corn hybrid that fully utilizes the optimal growing season duration (GDD).
- Use very high plant population (40,000 plants/acre).
- Grow under stress-free conditions.

Average irrigated corn yield in Nebraska by crop reporting district in the NASS database (1998-2002) and corresponding simulation of yield potential by the Hybrid-Maize model. Simulation is based on the current reported cropping practices (reported planting and maturity dates, 30,000 plants/acre).

Optimal management: *gain in season length*

Simulated full-season corn yield potential across Nebraska in comparison with actual average yields of irrigated corn (means of 1998-2002). Simulation assumes full utilization of the available growing season (optimal planting and choice of corn hybrid, 40,000 plants/acre).

Full season maize yield potential simulated by Hybrid-Maize compared to the yield of Nebraska yield contest winners (irrigated corn category).

2003	273	256	285	312	325	302	262

Potential applications

Using real-time climate data for a growing season :

- Estimate actual yield potential and water-limited attainable yield based on daily records of solar radiation, temperature, rainfall, and irrigation.
- Management decisions:
 - adjust yield goal during the season and make subsequent adjustments in fertilizer amounts (sidedress, fertigation)
 - evaluate moisture status and make decisions on irrigation.
 - evaluate actual plant growth and soil moisture dynamics in comparison with normal years/other years.
 - make decisions for next year.

Dryland corn, Mead 2003

Summary

- Models are not perfect representations of the real world. They represent the current scientific understanding in relatively simple mathematical terms.
- Hybrid-Maize is a robust model for estimating corn yield potential under non-limiting and water limiting conditions.
- Model estimates allow evaluating different options for crop management.
- Hybrid-Maize has promising potential for in-season management decisions.

Outlook

- Do more validation at other sites and for dryland corn.
- Write user's manual and release software in early 2004.
- More testing in real-time field management.
- Incorporate nitrogen management module.
